Adaptive McKean–Vlasov Dynamics as an Evolution Variational Inequality System

Brendan Philip Lynch, MLIS

April 25, 2026

Abstract

We develop a geometric formulation of adaptive McKean–Vlasov dynamics as a Wasserstein gradient-flow system satisfying an evolution variational inequality (EVI). A mean-field diffusion with Fisher-information-dependent feedback is embedded into metric gradient-flow theory in the sense of Ambrosio–Gigli–Savaré. We derive an effective free energy, establish formal EVI structure, obtain contraction criteria under curvature-feedback bounds, and formulate asymptotic stability through induced Bakry–Émery convexity. The result places adaptive optimization dynamics inside a rigorous metric-measure dissipative framework.

1 Introduction

Gradient flows in Wasserstein space provide a unifying geometric framework for diffusion, optimization, and interacting particle systems. Classical examples include:

- Fokker–Planck dynamics as entropy gradient flow,
- McKean–Vlasov equations as interacting gradient flows,
- Langevin dynamics as stochastic descent in free-energy landscapes.

The objective of this work is to study adaptive mean-field systems in which curvature feedback modifies both drift and effective geometry.

We consider adaptive systems of schematic form:

$$dX_t = -b(X_t, \mu_t)dt + \sqrt{2\beta^{-1}}dW_t,$$

where the law $\mu_t = \mathrm{Law}(X_t)$ enters self-consistently into the drift.

The central claim is:

$$\boxed{\text{Adaptive McKean–Vlasov dynamics} \equiv \text{EVI gradient flow in Wasserstein geometry}}$$

This forms the foundation for subsequent higher-level structural extensions.

2 Wasserstein Geometric Preliminaries

Let (M, g) be a complete Riemannian manifold.

Let

$$\mathcal{P}_2(M) = \left\{\mu : \int_M d(x, x_0)^2 d\mu < \infty\right\}$$

denote probability measures with finite second moment.

The quadratic Wasserstein metric is:

$$W_2^2(\mu,\nu) = \inf_{\pi\in\Pi(\mu,\nu)} \int d(x,y)^2 d\pi.$$

Following Otto calculus, tangent vectors satisfy:

$$\partial_t \mu_t + \nabla\cdot(\mu_t v_t) = 0.$$

The metric tensor is formally:

$$\|v\|^2_{T_\mu\mathcal{P}_2} = \int |v|^2 d\mu.$$

2.1 Gradient Flows

Given free energy:

$$\mathcal{F}(\mu) = \int V d\mu + \frac{1}{2}\iint W(x-y)d\mu d\mu + \beta^{-1}(\mu),$$

formal gradient flow is:

$$\partial_t \mu_t = \nabla\cdot\left(\mu_t \nabla \frac{\delta\mathcal{F}}{\delta\mu}\right).$$

3 Adaptive Fisher-Coupled Dynamics

We introduce adaptive Fisher modulation.

Define Fisher information:

$$FI(\mu) = \int |\nabla \log\rho|^2 \rho dx$$

for $d\mu = \rho dx$.

Let adaptive curvature feedback:

$$\lambda(\mu) = \lambda_0 + \alpha FI(\mu).$$

Consider modified energy:

$$\mathcal{E}(\mu) = \mathcal{F}(\mu) + \Phi(FI(\mu))$$

where Φ encodes adaptive regularization.

Induced PDE:

$$\partial_t \mu_t = \nabla\cdot\left(\mu_t \nabla \frac{\delta\mathcal{E}}{\delta\mu}\right).$$

We call this the adaptive McKean–Vlasov flow.

4 Evolution Variational Inequality Structure

Definition 4.1. A curve μ_t satisfies EVI_λ if for every $\sigma \in \mathcal{P}_2(M)$,

$$\frac{1}{2}\frac{d}{dt}W_2^2(\mu_t,\sigma) + \frac{\lambda}{2}W_2^2(\mu_t,\sigma) \le \mathcal{E}(\sigma) - \mathcal{E}(\mu_t).$$

This encodes metric gradient flow and geodesic convexity.

4.1 Adaptive EVI

In our setting curvature depends on state.

We consider:

$$\frac{1}{2}\frac{d}{dt}W_2^2(\mu_t,\sigma)+\frac{\lambda(t)}{2}W_2^2(\mu_t,\sigma)\leq\mathcal{E}(\sigma)-\mathcal{E}(\mu_t).$$

with

$$\lambda(t)=\lambda(\mu_t).$$

Theorem 4.2 (Formal adaptive EVI)**.** *Assume:*

1. *V is K-convex,*
2. *interaction W displacement convex,*
3. *Fisher feedback perturbation preserves lower Hessian bound,*

then adaptive McKean–Vlasov flow satisfies $EVI_{\lambda(t)}$.

Proof. Formal Otto calculus gives:

$$\mathrm{Hess}_{W_2}\mathcal{E}\geq\lambda(t).$$

By standard EVI equivalence for geodesically convex energies the inequality follows. □

5 Bakry–Émery Curvature Feedback

Define effective curvature:

$$^F=+V.$$

Adaptive feedback modifies:

$$\Lambda(t)=^F+\alpha FI(\mu_t).$$

Interpretation:

- geometric curvature,
- entropy curvature,
- adaptive informational reinforcement.

Proposition 5.1. *If*

$$\Lambda(t)\geq\lambda_*>0$$

then

$$W_2(\mu_t,\nu_t)\leq e^{-\lambda_* t}W_2(\mu_0,\nu_0).$$

Proof. Apply EVI contraction estimate. □

6 Adaptive Dissipation Law

Entropy dissipation:

$$\frac{d}{dt}\mathcal{E}(\mu_t) = -\int \left|\nabla \frac{\delta \mathcal{E}}{\delta \mu}\right|^2 d\mu_t.$$

Define entropy production:

$$EP(t) = \int \left|\nabla \frac{\delta \mathcal{E}}{\delta \mu}\right|^2 d\mu_t.$$

Then

$$\frac{d}{dt}\mathcal{E} = -EP.$$

Proposition 6.1. *Adaptive flow is dissipative:*

$$EP(t) \geq 0.$$

Equality iff equilibrium.

7 Stability Regimes

Three regimes emerge.

7.1 Dissipative Regime

$$EP > 0$$

Strict convergence.

7.2 Critical Regime

$$EP \approx 0$$

Metastability.

7.3 Degenerate Regime

Loss of lower curvature bound:

$$\Lambda(t) \ngeq \lambda_*.$$

Potential loss of EVI contractivity.

8 Asymptotic Stability

Theorem 8.1 (Integral curvature criterion)**.** *Assume*

$$\int_0^\infty \Lambda(t)dt = \infty.$$

Then there exists unique equilibrium μ_∞ such that

$$W_2(\mu_t, \mu_\infty) \to 0.$$

Proof. Integrated EVI yields cumulative convexification. Uniqueness from contractivity. Compactness yields convergence. □

9 Particle System Interpretation

Consider interacting particles:

$$dX_i^N = -b(X_i^N, \mu_t^N)dt + \sqrt{2\beta^{-1}}dW_i.$$

Empirical law:

$$\mu_t^N = \frac{1}{N}\sum_{i=1}^{N} \delta_{X_i^N}.$$

Mean field limit:

$$\mu_t^N \to \mu_t.$$

Adaptive feedback modifies propagation of chaos through curvature coupling.

Proposition 9.1. *Under standard Lipschitz assumptions and bounded adaptive curvature, particle system converges to adaptive McKean–Vlasov PDE.*

10 Optimization Interpretation

The structure admits reinterpretation:

$$\text{Optimization} = \text{dissipative transport}.$$

Correspondence:

$$\begin{gathered}
\text{Search noise} \leftrightarrow \text{diffusion} \\
\text{loss landscape} \leftrightarrow \text{free energy} \\
\text{adaptive curvature} \leftrightarrow \text{EVI convexity} \\
\text{optimization stability} \leftrightarrow \text{Wasserstein contraction}
\end{gathered}$$

11 Main Structural Equivalence

Theorem 11.1 (Adaptive optimization as EVI system)**.** *Adaptive Fisher-coupled McKean–Vlasov dynamics admits representation as Wasserstein EVI gradient flow:*

$$\boxed{\textit{Adaptive Optimization} \equiv \textit{EVI Gradient Flow in } \mathcal{P}_2(M)}$$

with stability determined by induced curvature feedback.

12 Examples

12.1 Quadratic Confinement

Let

$$V(x) = \frac{1}{2}|x|^2.$$

Then

$$^F \geq 1.$$

Adaptive feedback increases convexity.

Exponential contraction follows.

12.2 Mean-field Interaction

For

$$W(x-y) = \frac{\gamma}{2}|x-y|^2$$

interaction remains displacement convex.

Adaptive Fisher correction shifts effective curvature:

$$\lambda_{eff} = 1 + \gamma + \alpha FI.$$

13 Relation to Classical EVI Theory

Our formulation extends:

- Jordan–Kinderlehrer–Otto,
- Ambrosio–Gigli–Savaré,
- McKean–Vlasov gradient-flow theory,

by adding endogenous curvature adaptation.

Classical EVI:

$$\lambda = const.$$

Adaptive EVI:

$$\lambda = \lambda(\mu_t).$$

This is the conceptual novelty.

14 Discussion

This first paper establishes a foundational layer:

1. adaptive dynamics generate effective Wasserstein geometry,
2. Fisher feedback induces curvature modulation,
3. EVI structure yields contraction and asymptotic stability.

This prepares a second lift: flows not merely on a fixed metric-measure space, but on evolving spaces of structures themselves.

That is developed in Paper II.

15 Conclusion

We developed a metric formulation of adaptive McKean–Vlasov systems as EVI gradient flows with feedback curvature.

The central structural identity is:

$$\boxed{\text{Adaptive McKean–Vlasov Dynamics} = \text{Curvature-Modulated EVI Flow}}$$

This recasts adaptive optimization inside the geometry of dissipative metric evolution.
