Abstract

Building on Papers I–IX, we formulate a conditional renormalization framework for computational complexity within the UFT-F hierarchy.

Boolean circuit complexity is embedded into the hierarchical state space through spectral encodings and reconstruction functors.

The No-Compression Hypothesis (NCH) is reformulated as an admissibility condition controlling whether complexity data lie in a finite renormalized sector or exhibit persistent residue obstructions.

Within a Hopf-algebraic renormalization picture, the distinction between polynomial-time structure and nontrivial witness complexity is interpreted through fixed-point compatibility of the universal spectral-RG flow.

No unconditional proof of P $\neq$ NP is claimed; rather a structural synthesis is proposed.

1 Introduction

Papers I–IX developed a unified hierarchy in which:

$$\text{optimization} \rightsquigarrow \text{contractive spectral-RG flow.}$$

Paper X extends that architecture into computational complexity.
The organizing heuristic is:

$$\text{complexity data} \rightsquigarrow \text{renormalized spectral residue structure.}$$

Rather than replacing standard complexity theory, we provide a structural embedding.

2 Circuit Reconstruction Functor

Let

$$\mathcal{C}_n$$

denote Boolean circuits on n variables.

Definition 2.1 (Complexity Reconstruction Functor)**.** *Define*

$$\mathcal{R} : \mathcal{C}_n \to \Xi$$

by

$$\mathcal{R}(C) = (J_C, V_C).$$

where:

- J_C *is a spectral/Jacobi encoding,*
- V_C *is an effective reconstructed potential.*

Complexity information is represented through analytic properties of

$$V_C.$$

Remark 2.2. *This is a model encoding of circuit structure, not an identification of classical complexity classes with spectral theory per se.*

3 No-Compression Admissibility

Definition 3.1 (NCH Admissibility)**.** *A family of circuit encodings is called NCH-admissible if there exists no admissible renormalization reducing exponential witness complexity into uniformly polynomial encoding while preserving spectral invariants.*

Assumption 3.2. *All circuit families considered satisfy NCH admissibility.*

Remark 3.3. *NCH is treated here as a structural hypothesis, not proven inside this paper.*

4 Hopf Renormalization of Complexity Data

Let

$$\phi_C = \phi_-^{-1}(C)\phi_+(C)$$

be the Birkhoff factorization associated to a circuit encoding.
Interpret:

$$\phi_+$$

as finite renormalized computational structure,
and

$$\phi_-$$

as persistent residue obstruction.

Definition 4.1 (Complexity Correspondence)**.** *Heuristically:*

- *Polynomial structure corresponds to dominance of finite renormalized sector.*
- *NP-type witness complexity corresponds to nontrivial residue obstructions.*

Conjecture 4.2 (Renormalized Complexity Correspondence)**.** *Under NCH admissibility:*

$$P \quad \textit{corresponds to fixed-point-compatible encodings}$$

while

$$NP\textit{-complete}$$

corresponds to encodings exhibiting persistent renormalization obstruction.

5 ACI Regulator Floor and Spectral Stability

Definition 5.1. *Assume a regulator floor*

$$C_{UFT-F} > 0$$

such that:

$$\mathrm{Spec}(J_C^2) \subset [C_{UFT-F}, \infty].$$

This is interpreted as preventing collapse of spectral distinctions under admissible deformations.

Proposition 5.2. *Under ACI regulator-floor admissibility:*

(i) spectral encodings remain stable,

(ii) witness-complexity obstructions cannot be removed by admissible perturbation,

(iii) complexity classes remain spectrally distinguishable inside the model.

6 Compatibility with the Master Generator

Under Paper VII:

$$\frac{d\Xi}{dt} = \mathcal{G}(\Xi).$$

Theorem 6.1 (Conditional Complexity Compatibility)**.** *Assume:*

(A1) Paper VII closure hypotheses,

(A2) NCH admissibility,

(A3) ACI regulator-floor condition,

(A4) spectral index rigidity.

Then the computational layer is compatible with the universal semigroup

$$S_t = e^{t\mathcal{G}}.$$

Sketch. Combine:

- spectral coercivity,
- renormalization decomposition,
- reconstruction stability,
- Paper VII global attractor theory.

□

7 Conditional Fixed-Point Interpretation

Theorem 7.1. *There exists a computational sector*

$$\Omega^*_{comp} \subset \Omega^*$$

compatible with the universal attractor.
Polynomial computational structure is interpreted as compatibility with

$$\mathrm{Fix}(\mathcal{G}),$$

while residue obstructions correspond to failure of full fixed-point reduction.

8 Structural Synthesis

Within this framework:

$$\text{Complexity} \cong \text{Renormalized Spectral Residue Structure.}$$

and

$$\boxed{P/NP \text{ distinction} \subset \text{fixed-point compatibility problem}}$$

subject to NCH and ACI admissibility.

9 Conclusion

Paper X embeds computational complexity into the UFT-F hierarchy.

Its structural claims are:

1. circuits admit conditional spectral embedding,
2. NCH functions as admissibility hypothesis,
3. complexity admits Hopf-renormalization interpretation,
4. complexity separation is recast as a fixed-point compatibility problem.

Thus complexity theory is incorporated into the same conditional closure architecture developed in Papers I–IX.

$$\boxed{\text{Complexity Theory} = \text{Conditional Spectral-RG Sector}}$$
