Paper XIII: Renormalization of Yang–Mills Theory: Spectral Gap Admissibility, Hopf Counterterms, and Mass-Gap Fixed Points

Brendan Philip Lynch, MLIS

April 26, 2026

Abstract

Building on Papers I–XII, we formulate a renormalized embedding of the Yang–Mills existence and mass-gap problem into the UFT-F hierarchy. Gauge fields are treated as admissible spectral data in the enlarged hierarchical state space Ξ, while renormalization is expressed through a Hopf-algebraic Birkhoff decomposition of gauge amplitudes.

The Anti-Collision Identity (ACI) is reformulated as a spectral-gap admissibility condition governing constructive stability of the Yang–Mills Hamiltonian. Under this framework, the mass gap emerges as a fixed-point spectral residue of the universal dissipative flow rather than as an independent postulate.

This identifies confinement, constructive existence, and gap positivity as manifestations of a common renormalized spectral closure principle.

1 Introduction

Papers V–XII developed a renormalization architecture in which stability, index rigidity, and dissipative closure arise from a universal spectral-RG flow. This paper extends that framework to Yang–Mills theory.

Rather than treating the existence problem and mass gap separately, we interpret both as admissibility consequences of one operator-theoretic closure structure.

The central principle is:

> A Yang–Mills sector is physically admissible precisely when its associated spectral data lie entirely in the renormalized finite sector of the UFT-F hierarchy.

2 Spectral Reconstruction of Gauge Fields

Let $\mathcal{A}_{\mathrm{YM}}$ denote the moduli of admissible $\mathrm{SU}(N)$ connections over $\mathbb{R}^4$.

Definition 2.1 (Gauge Reconstruction Functor)**.** *Define*

$$\mathcal{R} : \mathcal{A}_{\mathrm{YM}} \to \Xi$$

by

$$\mathcal{R}(F) = (\mathcal{A}_F, \mathcal{H}_F, \mathcal{D}_F)$$

where $\mathcal{D}_F$ is the induced Dirac-type operator associated to gauge curvature F.

Its spectral zeta function is

$$\zeta_{\mathcal{D}_F}(s) = \mathrm{Tr}(|\mathcal{D}_F|^{-s}).$$

The Yang–Mills action is interpreted as spectral action

$$S_{YM} = \mathrm{Tr} f(\mathcal{D}_F/\Lambda).$$

Constructive existence is recast as stability of this spectral datum.

3 ACI as Yang–Mills Admissibility Condition

Definition 3.1 (ACI Spectral Admissibility)**.** *A Yang–Mills sector is ACI-admissible if:*

$$V_F \in L^1 \cap \textit{Kato class}$$

and

$$\mathrm{Spec}(\mathcal{D}_F^2) \subset [C_{UFT-F}, \infty)$$

for

$$C_{UFT-F} > 0.$$

Remark 3.2. *This lower bound acts as a regulator floor preventing ultraviolet collapse of the gauge spectrum.*

Assumption 3.3 (Yang–Mills Admissibility)**.** *All gauge sectors considered satisfy the ACI regulator-floor condition.*

Proposition 3.4. *Under ACI admissibility:*

1. *$\mathcal{D}_F$ remains essentially self-adjoint;*
2. *the spectral action remains finite;*
3. *the constructive Hamiltonian lies in a stable Fredholm class;*
4. *singularity-producing ultraviolet trajectories are excluded.*

4 Hopf-Algebraic Renormalization of Gauge Amplitudes

Let ϕ_F denote the character associated with the gauge sector.

Its Birkhoff decomposition is

$$\phi_F = \phi_-^{-1}\phi_+.$$

Interpret:

- ϕ_-: ultraviolet counterterm structure;
- ϕ_+: renormalized finite gauge amplitude.

Conjecture 4.1 (Yang–Mills Renormalization Correspondence)**.** *Constructive existence is equivalent to*

$$\phi_- = \varepsilon$$

after admissible subtraction.

Thus existence is a statement of complete renormalizability.

5 Mass Gap as Fixed-Point Spectral Residue

Mass-gap positivity is reformulated as spectral gap persistence.

Define

$$\Delta = \inf \operatorname{Spec}(\mathcal{D}_F^2) \setminus \{0\}.$$

Theorem 5.1 (Conditional Mass-Gap Fixed Point Principle)**.** *Assume:*

1. *ACI admissibility,*
2. *Paper VI index rigidity,*
3. *spectral closure hypotheses of Paper VII.*

Then

$$\Delta \geq C_{UFT-F} > 0.$$

Structural Proof. By ACI admissibility, the gauge spectrum cannot collapse below the regulator floor.

Index rigidity excludes spectral bifurcation into zero-energy continuous modes.

The dissipative flow

$$\frac{d\Xi}{dt} = \mathcal{G}(\Xi)$$

is contractive, hence every admissible gauge trajectory converges toward a stable fixed-point sector in Ω^* preserving a positive spectral gap. □

6 Base-24 Quantization as Spectral Ansatz

The Base-24 quantization principle is interpreted as a quantized realization of the abstract gap bound:

$$\Delta = 24\,\delta_0$$

for an elementary spectral scale δ_0.

Remark 6.1. *Within this formulation, Base-24 is not an independent axiom but a possible arithmetic realization of the renormalized mass-gap residue.*

This places the arithmetic quantization layer subordinate to the operator-theoretic gap theorem.

7 Confinement as Attractor Phenomenon

Confinement is interpreted as convergence of gauge trajectories to the universal attractor:

$$\lim_{t\to\infty} \mathcal{G}_t(F) = \Omega^*|_{YM}.$$

Thus confinement is reinterpreted as a fixed-point phenomenon of universal spectral renormalization.

8 Main Structural Synthesis

Theorem 8.1 (Conditional Yang–Mills Closure Principle)**.** *Under admissibility, index rigidity, and spectral closure hypotheses, constructive existence and mass-gap positivity arise as necessary compatibility conditions of the UFT-F hierarchy.*

9 Conclusion

Yang–Mills theory is recast as a renormalized spectral fixed-point sector of the universal hierarchy.

Within this framework:

- existence corresponds to admissible finite-sector closure,
- the mass gap corresponds to stable spectral residue,
- confinement corresponds to attractor convergence.

The Yang–Mills problem thus appears as a special instance of universal spectral closure rather than an isolated phenomenon.
