Abstract

Building upon Papers I–VII and the Standard Model embedding of Paper XIV, we formulate a renormalized embedding of neutrino spectral data into the hierarchical state space Ξ.

Rather than treating neutrino masses, PMNS observables, and leptonic CP phases as independent phenomenological inputs, we interpret them as admissible finite-sector residues generated by the universal dissipative renormalization flow.

Within this framework:

- the neutrino Jacobi block is promoted to spectral input for the Reconstruction Functor;
- the Anti-Collision Identity (ACI) becomes a regulator-floor admissibility condition preventing collapse of the low-mass sector;
- Majorana structure is formulated as a privileged conditional fixed-point topology;
- PMNS mixing and leptonic CP observables are modeled as torsional residues of the finite renormalized sector.

This places the neutrino sector inside the globally stable, operator-algebraic architecture of the UFT-F hierarchy as a conditional spectral subsystem.

1 Introduction

Papers I–VII established a closed mathematical hierarchy based on:

1. Contractive Evolution Variational Inequality dynamics;
2. Hopf-algebraic Birkhoff renormalization;
3. Index-rigid convergence under the master semigroup

$$\frac{d\Xi}{dt} = \mathcal{G}(\Xi)$$

toward the universal attractor Ω^*.

Paper XIV embedded the Standard Model particle sector into that hierarchy. Paper XV isolates the neutrino layer, which is analytically distinguished by:

- extremely small mass scales,
- nontrivial flavor mixing,
- unresolved Dirac versus Majorana topology,
- torsion-sensitive CP structure.

The objective is not to replace neutrino phenomenology, but to interpret observed neutrino data as admissible fixed-point structures inside the UFT-F renormalization framework.

2 Neutrino Reconstruction Functor

We define the neutrino reconstruction functor

$$\mathcal{R} : \mathcal{N} \to \Xi$$

mapping neutrino spectral data into the universal hierarchical state space.
Let

$$J_\nu = \begin{pmatrix} a_1 & b_1 & 0 \\ b_1 & a_2 & b_2 \\ 0 & b_2 & a_3 \end{pmatrix}$$

denote the Jacobi spectral block.

Associated Dirac dynamics are encoded through

$$\mathcal{D}_\nu = D_0 + \Phi(J_\nu).$$

3 Spectral Admissibility and ACI Floor

Definition 3.1 (Neutrino Spectral Admissibility)**.** *The neutrino sector is admissible provided:*

$$J_\nu \in L^1 \cap K$$

with K the Kato class, and

$$\mathrm{Spec}(\mathcal{D}_\nu) \subset [C_{UFT-F}, \infty)$$

where

$$C_{UFT-F} \approx 0.003119.$$

Remark 3.2. *The ACI acts as a spectral hard-deck preventing degenerate collapse of near-zero mass states.*

In this interpretation, the regulator floor is not an ultraviolet cut-off, but a structural admissibility constraint.

Assumption 3.3 (Neutrino ACI Compatibility)**.** *Throughout, all neutrino spectral data are assumed compatible with the ACI regulator-floor condition.*

4 Reconstruction Compatibility Theorem

Theorem 4.1 (Conditional Reconstruction Compatibility)**.** *Assume:*

1. *EVI Master Stability (Paper I),*
2. *Reconstruction Functor closure (Paper VII),*
3. *Index Rigidity (Paper VI),*
4. *ACI regulator admissibility.*

Then the neutrino subsystem admits a compatible embedding

$$\mathcal{R}(J_\nu) \subset \Omega^*$$

as a conditionally stable renormalized sector.

Proof. Under the stated hypotheses, the induced Dirichlet form remains coercive, the spectral lower bound prevents degeneracy, and contractive EVI evolution implies convergence toward a stable fixed-point component.

Compatibility follows.

□

5 Hopf Renormalization of Neutrino Data

Let

$$\phi_\nu = \phi_-^{-1}\phi_+$$

be the neutrino-sector Birkhoff factorization.

Interpret:

- ϕ_- : divergent counterterm sector;
- ϕ_+ : finite renormalized neutrino observables.

Conjecture 5.1 (Neutrino Data as Finite Residues)**.** *Masses and PMNS observables are encoded entirely in*

$$\phi_+(\nu).$$

6 Conditional Majorana Fixed-Point Principle

Proposition 6.1. *Assume:*

1. *ACI admissibility,*
2. *index-rigid closure,*
3. *finite-sector purity*

$$\phi_- = \varepsilon.$$

Then Majorana-type neutrino structure defines a privileged compatible fixed-point sector.

Remark 6.2. *This is intentionally a conditional compatibility result, not an unconditional exclusion theorem for Dirac sectors.*

7 Neutrino Mass Hierarchies as Fixed-Point Data

Let

$$\lambda_1, \lambda_2, \lambda_3$$

denote neutrino spectral eigenvalues.

Proposition 7.1. *Masses admit fixed-point representation*

$$m_i = F_i(\lambda_i, C_{UFT-F}).$$

A model spectral ansatz:

$$m_i = F_i(C_{UFT-F}, \omega_i).$$

Possible total mass constraint:

$$\sum_i m_i = M_\nu^*$$

for fixed-point value determined by the chosen spectral ansatz.

8 PMNS Mixing and Torsional Residues

Define torsion invariant:

$$\omega_u.$$

Mixing observables modeled by

$$|U_{\alpha i}|^2 = F_{mix}(\omega_u, C_{UFT-F}).$$

Conjecture 8.1. *Leptonic CP violation arises as finite torsional residue inside ϕ_+.*

Jarlskog ansatz:

$$J_{CP} = F_{CP}(\omega_u, C_{UFT-F}).$$

9 Conditional Neutrino Fixed Point Principle

Define full interacting hierarchy

$$\Xi = (\mu, g, D, \Gamma, \nu).$$

Theorem 9.1. *Assume:*

1. *EVI stability,*
2. *Hopf renormalizability,*
3. *Index rigidity,*
4. *ACI admissibility.*

Then the neutrino layer is compatible with

$$\frac{d\Xi}{dt} = \mathcal{G}(\Xi)$$

and evolves toward a stable fixed-point sector inside

$$\Omega^*.$$

Corollary 9.2. *Neutrino masses and PMNS observables may be interpreted as conditionally stable spectral residues of the universal dissipative hierarchy.*

10 Conclusion

Paper XV embeds the neutrino sector into the foundational UFT-F renormalization hierarchy as a conditional fixed-point subsystem.

Within this framework:

- neutrino masses become renormalized spectral residues,
- PMNS observables become torsional fixed-point data,
- Majorana topology becomes a privileged admissible sector,
- the ACI supplies the regulator floor ensuring low-mass sector stability.

Thus neutrino phenomenology is recast as structured compatible spectral data within the universal dissipative hierarchy.
