Abstract

Building upon the axiomatic closure of Papers I–VII and the Standard Model embeddings of Papers XIV–XV, we formulate a renormalized embedding of quark masses, Cabibbo–Kobayashi–Maskawa (CKM) mixing data, and confinement structure into the UFT-F hierarchy.

Rather than treating flavor hierarchies and CP observables as arbitrary phenomenological parameters, we interpret them as admissible finite-sector spectral residues generated by a universal renormalization flow.

Within this framework:

- quark flavor data are represented through a Quark Reconstruction Functor;
- confinement appears as an index-rigid admissible topology;
- CKM observables arise as renormalized fixed-point residues;
- BRST cohomological closure constrains gauge consistency;
- CP violation is interpreted as torsional residue data in the finite sector.

This establishes the quark flavor sector as a conditionally stable fixed-point layer inside the universal attractor Ω^*.

1 Introduction

Papers I–VII established a universal hierarchy characterized by

1. EVI contractive dynamics on metric-measure spaces,
2. Hopf-algebraic Birkhoff renormalization,
3. index-rigid topological closure,
4. dissipative evolution toward the attractor Ω^*.

Papers XIV and XV embedded Standard Model and neutrino data into that structure. This manuscript isolates the quark sector, whose difficult features include:

- extreme mass hierarchies,
- nontrivial CKM mixing,
- color confinement,
- CP violation.

The objective is not to claim derivation of measured flavor values from first principles, but rather to show these observables may be represented as conditionally admissible fixed-point residues inside the renormalized hierarchy.

2 Quark Reconstruction Functor

Define the quark reconstruction functor

$$\mathcal{R}_q : \mathcal{Q} \longrightarrow \Xi$$

mapping quark spectral data into the hierarchical state space.

Let

$$J_q$$

denote the Jacobi flavor block encoding the six quark sectors.
Associated Dirac dynamics:

$$\mathcal{D}_q = D_0 + \Phi(J_q)$$

where Φ intertwines flavor geometry with the master spectral flow.

Definition 2.1 (Flavor Spectral Admissibility)**.** *The quark sector is admissible provided*

$$J_q \in L^1 \cap \mathrm{Kato}$$

and

$$\mathrm{Spec}(\mathcal{D}_q) \subset [C_{UFT-F}, \infty)$$

with regulator floor

$$C_{UFT-F} \approx 0.003119.$$

Remark 2.2. *The Anti-Collision Identity acts as regulator floor preventing flavor-sector spectral degeneration.*

Assumption 2.3. *Throughout this paper we assume all flavor-sector data satisfy ACI admissibility.*

3 Hopf-Algebraic Flavor Renormalization

Let

$$\phi_q : \mathcal{H}_{FG} \to \mathcal{A}$$

be the quark-sector character.
Its Birkhoff decomposition is

$$\phi_q = \phi_-^{-1}\phi_+.$$

Interpretation:

- ϕ_-: counterterm/divergent sector
- ϕ_+: finite renormalized flavor observables

Conjecture 3.1 (Flavor Residue Principle)**.** *Observed quark masses and CKM observables admit representation within finite-sector residues*

$$\phi_+(q).$$

This is a reconstruction hypothesis, not a uniqueness theorem.

4 Gauge Consistency and BRST Closure

To ensure compatibility with gauge renormalization, we impose cohomological consistency.

Definition 4.1 (BRST Closure)**.** *The quark reconstruction functor is BRST compatible if*

$$H^0_{\mathrm{BRST}}(\mathcal{R}_q) = 0$$

and admissible spectral flows preserve gauge cohomology.

Proposition 4.2 (Slavnov–Taylor Compatibility)**.** *Assume BRST closure and ACI admissibility.*

Then finite-sector residues generated by Birkhoff factorization preserve Slavnov–Taylor identities under the renormalization flow.

Remark 4.3. *This connects the UFT-F renormalization architecture to conventional gauge-theoretic consistency conditions.*

5 Confinement as Index-Rigid Topology

Rather than treating confinement purely dynamically, we model it as an admissible topological sector.

Definition 5.1 (Topological Confinement Sector)**.** *A confined quark sector corresponds to a double-well admissible topology represented by*

$$\mathrm{Ind}(D_F) = k.$$

Proposition 5.2. *Assume:*

1. *ACI admissibility*
2. *index rigidity*
3. *finite-sector purity:*

$$\phi_- = \varepsilon$$

Then confinement defines a distinguished admissible fixed-point sector.

Remark 5.3. *We do not claim SU(3) uniqueness from these axioms; rather SU(3) is treated as a distinguished admissible confinement realization.*

6 Renormalization Group Flavor Flow

To interpret flavor observables as fixed points, introduce beta-flow equations

$$\mu \frac{dF_{ij}}{d\mu} = \beta_{ij}(F, C_{UFT-F}).$$

Flavor fixed points satisfy

$$\beta_{ij} = 0.$$

Definition 6.1. *A CKM observable is called renormalized fixed-point compatible if*

$$|V_{ij}|^2 = F_{ij}(\omega_u, C_{UFT-F})$$

and

$$\beta_{ij} = 0.$$

Remark 6.2. *This gives literal RG meaning to the phrase "renormalized flavor fixed point."*

7 CKM Spectral Maps

Define a spectral ansatz

$$V_{CKM} = F_{CKM}(G_{24}, \omega_u).$$

Conjecture 7.1 (CKM Reconstruction Conjecture)**.** *Observed mixing data may be represented as stable residues induced by G_{24} projective spectral geometry.*

This is posed as reconstruction ansatz, not exact derivation.

8 CP Phase as Torsional Residue

Rather than asserting the measured CKM phase as uniquely forced, we formulate:

Conjecture 8.1. *CP violation arises from nontrivial torsional residue structure inside the finite renormalized sector.*

Model ansatz:

$$\delta_{CP} = F_{CP}(\omega_u, C_{UFT-F}).$$

The empirical value

$$\delta_{CP} \sim 69^\circ$$

is interpreted only as a candidate compatible fixed point of this torsional ansatz.

Remark 8.2. *This is not claimed as uniqueness theorem, but as conditional reconstruction hypothesis.*

9 Conditional Flavor Fixed Point Principle

Define total state

$$\Xi = (\mu, g, D, \Gamma, q).$$

Theorem 9.1 (Conditional Flavor Fixed Point Principle)**.** *Assume:*

1. *EVI stability*

2. *Hopf renormalizability*
3. *BRST closure*
4. *index rigidity*
5. *ACI regulator-floor admissibility*

Then the quark flavor layer is compatible with

$$\frac{d\Xi}{dt} = \mathcal{G}(\Xi)$$

and evolves toward a stable fixed-point sector inside Ω^*.

Corollary 9.2. *Flavor observables represented by admissible residue data remain invariant under fixed-point flow.*

10 Conclusion

Paper XVI embeds the quark sector into the UFT-F hierarchy as a conditional renormalized subsystem.

Within this framework:

- quark masses become admissible spectral residues;
- confinement appears as index-rigid topology;
- CKM observables admit RG fixed-point interpretation;
- BRST closure enforces gauge consistency;
- CP structure is modeled as torsional residue data.

Thus the flavor sector is interpreted not as arbitrary parameter data but as a structured admissible component of the universal dissipative hierarchy.

Future work concerns whether these reconstruction ansätze can be promoted from conditional compatibility statements to stronger derivation theorems.
