Abstract

We extend the renormalization program of Papers I–XVI into the logical and computational sector by introducing a spectral admissibility refinement of formal systems.

Rather than treating logical independence phenomena and computational extremality as disconnected foundational anomalies, we model them as admissibility questions inside the hierarchical state space Ξ.

Within this framework:

- the Anti-Collision Identity is lifted into the logical sector as the Axiom of Spectral Admissibility (ASA);
- Continuum Hypothesis independence is recast as a spectral selection problem relative to admissible embeddings;
- Busy Beaver extremality is interpreted through complexity saturation and ghost-state obstructions;
- these structures form the logical bridge into Spectral Figurate Geometry.

The result is not a replacement for classical metamathematics, but a physically constrained subcategory ZFC_{UFT} in which mathematical existence is identified with stable spectral integrability.

1 Introduction: Logic as a Spectral Subcategory

Papers I–VII introduced a dissipative hierarchy

$$\frac{d\Xi}{dt} = \mathcal{G}(\Xi)$$

with stable evolution toward the universal attractor

$$\Omega^*.$$

Papers XIV–XVI embedded particle and flavor structures into this hierarchy as admissible spectral residue sectors.

Paper XVII extends the same architecture into logic and computation.

The organizing thesis is:

$$\text{Existence} \quad \Longleftrightarrow \quad \text{Stable Spectral Admissibility.}$$

This motivates a refinement of ZFC.

Definition 1.1 (Spectrally Admissible Fragment)**.** *Define*

$$ZFC_{UFT} \subseteq ZFC$$

to be the subcategory of mathematical objects admitting stable trace-class embeddings into the hierarchical state space Ξ*.*

Thus ZFC_{UFT} supplements rather than replaces ordinary ZFC.

2 The Axiom of Spectral Admissibility

We lift the Anti-Collision Identity into the logical sector.

Definition 2.1 (Axiom of Spectral Admissibility)**.** *A set, structure, or computational trace* X *is spectrally admissible when:*

(i) its informational potential satisfies

$$\|V_{info}(X)\|_{L^1} < \infty,$$

(ii) its embedding lies in the Kato class,

(iii) its induced spectral flow does not violate index stability.

This criterion is denoted ASA.

Proposition 2.2 (ASA-ACI Correspondence)**.** *Within the UFT-F hierarchy,*

$$\text{ASA} \leftrightarrow \text{ACI}$$

as logical and physical manifestations of the same admissibility constraint.

Remark 2.3. *ASA functions as a spectral selection rule rather than a replacement axiom in the ordinary set-theoretic sense.*

3 Logical Reconstruction Functor

Introduce a logical reconstruction functor

$$\mathcal{R}_{\text{logic}} : \mathcal{L} \to \Xi.$$

This maps formal structures into the renormalized hierarchy.
The working principle is:

$$\text{Logical admissibility} \quad \Longrightarrow \quad \text{Spectral realizability.}$$

Objects failing this criterion are interpreted as non-faithful or ghost-state embeddings.

4 Metric Saturation and the Redundancy Cliff

We model finite informational saturation through the complexity threshold

$$\chi \approx 763.55827.$$

Definition 4.1 (Redundancy Cliff)**.** *The redundancy cliff is the spectral saturation boundary at which admissible residue structure can no longer be stably distinguished from divergent counterterm behavior.*

Motivated ansatz:

$$\chi = \frac{\rho_\Lambda \, \sigma \, \eta \, \mathcal{V}_{S^3}}{\pi}.$$

Conjecture 4.2 (Complexity Saturation Principle)**.** *Structures whose effective density exceeds χ enter a non-faithful embedding regime.*

5 Spectral Selection and the Continuum

We explicitly preserve the classical Gödel-Cohen independence theorem.

The proposal here is relative.

Theorem 5.1 (Continuum Selection Relative to ASA)**.** *Inside the admissible subcategory ZFC_{UFT}, intermediate cardinal structures*

$$\aleph_0 < |S| < 2^{\aleph_0}$$

fail spectral admissibility and are excluded as stable embeddings.

Consequently, relative to ASA, the continuum dichotomy is uniquely admissible.

Renormalization Sketch. Intermediate cardinal embeddings generate non-integrable torsional defects in the admissibility functor $\mathcal{R}_{\text{logic}}$.

These produce ghost-state obstructions violating index rigidity.

Therefore such objects are excluded inside ZFC_{UFT}. □

Remark 5.2. *This is a categorical admissibility theorem relative to ASA, not a negation of classical independence results.*

6 Busy Beaver and Complexity Saturation

We interpret Busy Beaver extremality through saturation.

Definition 6.1 (Ghost State)**.** *A ghost state is an embedding failure where distinct symbolic states lose injective metric distinction.*

Conjecture 6.2 (Turing-Schwarzschild Saturation Wall)**.** *Busy Beaver growth enters a complexity-saturation regime near the $BB(6)$ threshold in which admissible embedding fails.*

Symbolically:

$$K(T_{BB}) > \chi \quad \Longrightarrow \quad \text{Ghost-State Transition.}$$

Remark 6.3. *This treats $BB(6)$ as a proposed spectral transition wall rather than as a conventional theorem of computability.*

7 Index Rigidity in the Logical Sector

The organizing hypothesis is that logical admissibility obeys the same rigidity principle as earlier spectral sectors.

Proposition 7.1 (Logical Index Rigidity)**.** *Fredholm index stability in the logical sector is preserved only for spectrally admissible embeddings.*

Symbolically:

$$\text{Ind}(D) = \text{constant}$$

throughout admissible logical evolution.

Ghost-state emergence corresponds to attempted index jumps.

8 Bridge to Spectral Figurate Geometry

Paper XVII serves as the funnel into Spectral Figurate Geometry.

If

$$\text{Existence} = \text{Spectral Integrability},$$

then major analytical problems may be reformulated through shared admissibility constraints.

Heuristic reductions include:

1. P **vs** NP**:** complexity separation linked to saturation thresholds.
2. **Navier-Stokes:** regularity linked to the LIC floor.
3. **Yang-Mills:** mass gap linked to positive spectral-floor residues.

These remain forward structural heuristics to be formalized in Spectral Figurate Geometry.

9 Conclusion

Paper XVII extends UFT-F from physical renormalization into logical admissibility.

Its central claim is not:

"Classical logic is replaced,"

but rather:

$$\text{Physical realizability} \Longrightarrow \text{Spectral selection}.$$

Within this framework:

- ASA refines admissible logical existence;
- continuum structure is selected categorically relative to admissibility;
- computational extremality is interpreted through saturation walls;
- Spectral Figurate Geometry emerges as the natural next closure layer.

This establishes the logical sector as the final renormalized bridge before the SFG synthesis.
