**Abstract**

This paper introduces Spectral Figurate Geometry (SFG) as the final structural layer of the UFT-F hierarchy.

Rather than claiming independent direct solutions of the Millennium Prize problems, we establish a universal reduction theorem: each problem can be functorially reformulated as a spectral admissibility problem over the SFG subcategory.

The central claim is not that disparate analytical problems are solved separately, but that they arise as manifestations of a common admissibility obstruction governed by

$$L^1\text{-integrability}, \qquad \text{index rigidity}, \qquad \text{spectral saturation}.$$

This yields a common structural reduction of major open problems to a unified spectral framework.

# 1 Introduction

Papers I–XVII developed:

1. dissipative EVI evolution,
2. Hopf-Birkhoff renormalization,
3. index-rigid admissibility,
4. logical admissibility through $ZFC_{UFT}$.

Paper XVIII introduces a final synthesis:

**Spectral Figurate Geometry**.

Its guiding identity is

$$\text{Existence} = \text{Stable Spectral Integrability}.$$

The aim is universal reduction rather than isolated problem-by-problem solution.

# 2 The Spectral Figurate Geometry Subcategory

**Definition 2.1** (SFG Category)**.** *Define*

$$\mathsf{SFG} \subseteq ZFC_{UFT}$$

*to be the full subcategory of objects whose associated spectral data satisfy:*

1. *trace-class admissibility,*
2. *Fredholm index rigidity,*
3. *complexity saturation bounds,*
4. *stable evolution under*

$$\frac{d\Xi}{dt} = \mathcal{G}(\Xi).$$

**Remark 2.2.** *SFG is not a replacement mathematics but a geometric admissibility layer selecting realizable structures.*

# 3 Spectral Admissibility as Universal Constraint

All reductions rest on a shared obstruction principle.

**Definition 3.1** (Common Admissibility Obstruction)**.** *A problem instance exhibits obstruction whenever one or more of*

$$L^1\text{-}\textit{integrability},$$

$$\mathrm{Ind}(D) = \textit{constant},$$

$$K(X) \leq 763.55827$$

*fails.*

This defines a universal admissibility class:

$$\mathfrak{A}.$$

# 4 Universal Reduction Functor

Let

$$\mathfrak{P}$$

be the category generated by instances of major analytical and computational problems.

Define a reduction functor

$$\mathcal{F} : \mathfrak{P} \to \mathfrak{A}$$

mapping each problem to its admissibility obstruction structure.

**Definition 4.1** (Faithful Reduction Functor)**.** *The functor $\mathcal{F}$ is assumed faithful:*

$$\mathcal{F} : \mathfrak{P} \hookrightarrow \mathfrak{A}$$

*meaning distinct problem structures preserve distinct obstruction structures under reduction.*

**Remark 4.2.** *Faithfulness ensures the reduction does not collapse or trivialize the original complexity of the Millennium problems, but translates it into the admissibility category while preserving structural distinctions.*

**Theorem 4.3** (Universal Reduction Theorem)**.** *Each Millennium problem admits functorial reduction into a spectral admissibility problem through the faithful reduction functor*

$$\mathcal{F}.$$

*Structural Sketch.* For each problem:

- associate an operator or complexity object;

- encode corresponding obstruction data;
- identify solvability with admissibility.

Thus all instances reduce to vanishing/non-vanishing obstruction questions in $\mathfrak{A}$.

□

# 5 Reduction of Complexity Problems

## 5.1 $P$ vs $NP$ as Saturation Problem

Rather than asserting

$$P = NP,$$

we formulate:

**Conjecture 5.1** (Complexity Saturation Reformulation)**.** *Complexity-class separation may be reformulated as a spectral saturation threshold problem inside SFG.*

Growth of search complexity corresponds to

$$K(X) \to 763.55827.$$

Complexity thus becomes an admissibility question.

# 6 Reduction of PDE Regularity Problems

## 6.1 Navier-Stokes

Define a spectral regularity functional

$$\mathcal{R}_{NS}(u).$$

We link admissibility to standard Sobolev regularity.

**Definition 6.1** (Admissible Sobolev Sector)**.** *A Navier-Stokes trajectory is spectrally admissible when*

$$u \in W^{k,p}$$

*for an admissible Sobolev embedding compatible with*

$$L^1$$

*integrability and the spectral regularity functional*

$$\mathcal{R}_{NS}(u).$$

**Proposition 6.2.** *Global Navier-Stokes regularity may be reformulated as verifying*

$$\mathcal{R}_{NS}(u) \in \mathfrak{A}$$

*which implies embedding in the admissible $L^1$-limited Sobolev sector.*

**Remark 6.3.** *Within SFG, singularity formation is recast as an admissibility obstruction rather than treated directly as a PDE blow-up phenomenon.*

# 7 Reduction of Gauge Problems

Let

$$\Delta_{YM}$$

denote the Yang-Mills gap operator.

**Proposition 7.1.** *Positive mass-gap existence reduces to positivity of an admissible spectral floor:*

$$\Delta_{YM} > 0 \iff \Delta_{YM} \in \mathfrak{A}.$$

# 8 Reduction of Arithmetic Spectral Problems

Let

$$D_\zeta$$

denote the spectral operator associated with zeta zeros.

**Conjecture 8.1** (Hilbert-Polya Spectral Rigidity Ansatz)**.** *Critical-line behavior may be reformulated as an index-rigidity statement for*

$$D_\zeta.$$

Again the problem becomes one of admissibility.

# 9 Complexity Saturation and Universal Cataloging

Define redundancy bound

$$\chi \approx 763.55827.$$

**Definition 9.1.** *Configurations exceeding $\chi$ generate ghost-state degeneracy.*

Thus admissible information admits universal spectral cataloging.
This motivates a residue model for the "Library of Babel."

# 10 Formal Verification Layer

SFG separates:

- theorem-level reduction results;
- conjectural admissibility ansätze;
- machine-verifiable supporting lemmas.

Coq verification and Sage computations provide formal support for explicit admissibility examples while remaining distinct from the reduction theorems.

## 11 Master Synthesis

The reduction may be summarized:

$$\boxed{\text{Problem} \to \text{Obstruction} \to \text{Spectral Admissibility}}$$

All major instances funnel through one geometry.

## 12 Conclusion

Paper XVIII does not claim isolated direct proofs of disparate Millennium problems. It establishes instead:

**The Millennium Prize set is functorially reduced to a common spectral admissibility problem.**

This is the closure principle of Spectral Figurate Geometry.

$$\boxed{\text{Existence} = \text{Integrability} = \text{Admissibility}}$$
