Abstract

Building on Papers I–VIII, we formulate a conditional renormalization framework for the Hodge Conjecture inside the UFT-F hierarchy.

Inverse scattering reconstruction is interpreted as a specialized realization of the reconstruction functor, while Hodge classes are embedded into the hierarchical state space as spectral-geometric data.

The Apex/Trough Hypothesis (ATH) is recast as an admissibility condition controlling spectral stability, while the Anti-Collision Identity (ACI) appears as a regulator-floor constraint.

Under the analytic closure assumptions inherited from Paper VII, algebraicity of admissible Hodge data is interpreted as compatibility with fixed-point structure of the universal spectral-RG flow.

No unconditional proof of the Hodge Conjecture is claimed; rather a structural synthesis is given.

1 Introduction

The classical Hodge Conjecture states:

for smooth projective

$$X/\mathbb{C}$$

every rational Hodge class in

$$H^{2p}(X, \mathbb{Q}) \cap H^{p,p}(X)$$

should arise from algebraic cycles.

This paper develops a renormalized embedding of that problem into the UFT-F framework.

Guiding principle:

$$\text{Algebraic cycle data} \rightsquigarrow \text{fixed-point spectral data.}$$

2 Spectral Reconstruction of Hodge Data

Definition 2.1 (Hodge Reconstruction Functor)**.** *Define*

$$\mathcal{R} : H^{p,p}(X) \to \Xi$$

by assigning a Hodge class

$$\omega$$

to spectral data

$$\mathcal{R}(\omega) = (\mathcal{A}_\omega, \mathcal{H}_\omega, D_\omega).$$

In the inverse-scattering realization, reconstruction is modeled through a Gelfand-Levitan-Marchenko kernel

$$K(x, y)$$

with effective potential

$$V(x) = -2\frac{d}{dx}K(x, x).$$

Remark 2.2. *This is interpreted as a model realization of the reconstruction functor, not as a literal reduction of general Hodge theory to one-dimensional scattering.*

3 ATH Admissibility and Spectral Stability

Definition 3.1 (ATH Admissibility)**.** *A spectral realization of a Hodge class is called ATH-admissible if:*

(i) associated potentials satisfy

$$V \in L^1 \cap \textit{Kato class}$$

(ii) the spectral operator satisfies

$$\mathrm{Spec}(D_\omega^2) \subset [c_{UFT-F}, \infty]$$

for some regulator floor

$$c_{UFT-F} > 0$$

(iii) admissible perturbations preserve index class.

Assumption 3.2. *All Hodge classes considered satisfy ATH admissibility.*

Proposition 3.3. *Under ATH admissibility:*

(i) spectral realizations remain Fredholm,

(ii) spectral gaps are stable,

(iii) inverse-scattering reconstruction remains well posed.

4 Renormalization of Rational Constructibility

In the Hopf-algebraic framework of Paper V, decompose

$$\phi = \phi_-^{-1}\phi_+.$$

Interpret:

$$\phi_-$$

as divergent transcendental sector,
while

$$\phi_+$$

defines renormalized finite algebraic data.

Conjecture 4.1 (Rational Constructibility Correspondence)**.** *A Hodge class is algebraic precisely when its associated spectral character admits representation in the finite renormalized sector:*

$$\phi(\omega) = \phi_+(\omega).$$

Remark 4.2. *This should be read as a structural correspondence, not a replacement for the classical cycle-class problem.*

5 Index Rigidity and Fixed-Point Compatibility

Under Paper VII, the master generator satisfies

$$\frac{d\Xi}{dt} = \mathcal{G}(\Xi).$$

Theorem 5.1 (Conditional Hodge Compatibility)**.** *Assume:*

(A1) Paper VII closure hypotheses,

(A2) ATH admissibility,

(A3) ACI regulator-floor condition,

(A4) index rigidity under admissible homotopy.

Then the Hodge layer is compatible with the universal semigroup

$$S_t = e^{t\mathcal{G}}.$$

Sketch. Combine:

- spectral gap coercivity,
- Fredholm index rigidity,
- reconstruction stability,
- Paper VII attractor theory.

□

6 Conditional Fixed-Point Interpretation

Theorem 6.1. *Under the above assumptions, there exists*

$$\Omega^*_{Hodge} \subset \Omega^*$$

compatible with the universal attractor such that

$$S_t\Xi \to \Omega^*.$$

Hodge-theoretic algebraicity is interpreted as compatibility with

$$\mathrm{Fix}(\mathcal{G}).$$

7 Structural Synthesis

Within the UFT-F hierarchy:

$$\text{Hodge data} \cong \text{renormalized spectral fixed-point data.}$$

Thus:

$$\boxed{\text{Algebraicity} \subset \mathrm{Fix}(\mathcal{G})}$$

subject to ATH and ACI admissibility.

8 Conclusion

Paper IX extends the UFT-F hierarchy into Hodge theory.

Its structural claims are:

1. Hodge data admit conditional embedding into the hierarchy,
2. inverse scattering provides a reconstruction model,
3. ATH functions as spectral admissibility,
4. algebraicity may be interpreted as fixed-point compatibility.

Thus the Hodge layer is incorporated into the same conditional closure architecture as Papers I–VIII.

$$\boxed{\text{Hodge Geometry} = \text{Conditional Spectral-RG Sector}}$$
