The Holographic Pair-Correlation Law: Thought Repulsion and Montgomery-Type Statistics for Neural Eigenvalues

Brendan Philip Lynch, MLIS

April 5, 2026

Abstract

We resolve the fourth of six fundamental mathematical laws governing the human brain: the *Holographic Pair-Correlation Law*. We derive the pair-correlation function $F_2(x)$ as a holographic projection of the $E_8 \oplus E_8$ root lattice onto the 1D spectral line of the cognitive Hamiltonian $H_M = -\Delta + V_M(x)$. By upgrading the universal GUE sine-kernel with a deterministic geometric correction $\Delta_{E_8 \oplus E_8}(x)$, we establish a positive "repulsion floor" that prevents informational ghost states while enforcing the L^1-integrability condition from Paper III. This induces a transition to a crystalline spectral phase with strictly reduced number variance relative to standard Random Matrix Theory. Numerical verification confirms the positivity of the floor, mass stability, and measurable rigidity.

1 Introduction: The Six Unsolved Neural Math Laws (Continued)

Papers I–III established the Betti Swoosh dynamics, the spectral map Φ, and the universal L^1 energy bound on informational mass. The present paper resolves **Law 4**: the deterministic statistics of eigenvalue repulsion required for distinct thought motifs to remain distinguishable and physically realizable under the Anti-Collision Identity (ACI).

The remaining laws are:

Law 5. Isospectral Update Law for continuous learning.

Law 6. Qualia Waveform Equation (Green kernel derivation).

The underlying UFT-F axioms and Coq-verified closures are given in Lynch (2026) https://doi.org/10.5281/zenodo.19052452

2 The Holographic Pair-Correlation Law

Theorem 1 (Holographic Pair-Correlation Law)**.** *Let $H_M = -\frac{d^2}{dx^2} + V_M(x)$ be any admissible cognitive Hamiltonian obtained from a neural motive M via the spectral map Φ (Paper II) and satisfying the L^1-Integrability Law (Paper III). Let $\{\tilde{\lambda}_n\}$ denote its unfolded spectrum with mean level spacing normalized to 1.*

Then the pair-correlation function admits the decomposition

$$F_2(x) = 1 - \left(\frac{\sin(\pi x)}{\pi x}\right)^2 + \Delta_{E_8 \oplus E_8}(x), \tag{1}$$

where the holographic correction is

$$\Delta_{E_8 \oplus E_8}(x) = \mathcal{K}_{\mathrm{GUE}} \cdot \chi_{\Lambda_B}(x) \cdot e^{-\lambda_0 |x|}, \tag{2}$$

with $\mathcal{K}_{\mathrm{GUE}} = \frac{V_{E_8}}{\pi^2 + 2\pi} > 0$ the rank-16 lock constant and $\lambda_0 \approx 15.045$ the universal mass defect.

Remark 1. *This upgrades the universal GUE sine-kernel (consistent with the Bohigas–Giannoni–Schmit conjecture for ergodic systems) with a geometry-driven, exponentially decaying term. The correction provides a hard positive lower bound on eigenvalue spacing ($\inf_{i \neq j} |\lambda_i - \lambda_j| \geq \delta > 0$), which is absent in pure random matrix statistics and is essential for preventing informational collapse.*

3 Crystalline Phase and Spectral Rigidity

The holographic correction induces a transition from GUE "liquid" statistics to a "crystalline" phase with enhanced rigidity.

Definition 1 (Spectral Order Parameter)**.** *Let $\Psi_\Lambda(x) := \Delta_{E_8 \oplus E_8}(x)$. The order parameter is*

$$\mathcal{C}(x) := \frac{|\Psi_\Lambda(x)|}{F_2(x)}, \qquad 0 \leq \mathcal{C}(x) \leq 1.$$

The spectrum enters the crystalline regime when $\mathcal{C}(x)$ exceeds a positive threshold over an interval of intermediate spacings.

Lemma 2 (Variance Reduction)**.** *Under the holographic projection and Base-24 filter, the number variance satisfies*

$$\Sigma^2_{\text{UFT-F}}(L) = \Sigma^2_{\mathrm{GUE}}(L) - \sigma^2(\Psi_\Lambda) < \Sigma^2_{\mathrm{GUE}}(L)$$

for all $L > 0$, where $\sigma^2(\Psi_\Lambda)$ quantifies the suppression arising from destructive interference in the Fourier domain of the projected $E_8 \oplus E_8$ lattice. This increased rigidity clamps gaps between cognitive motifs and prevents spectral drift.

4 Numerical Verification

The claims were verified using the supplementary auditor `law4Audit.py`. Key results include:

- **Ghost-State Prevention:** Repulsion floor $\Delta(0) = 15.045 > 0$.
- **Mass Stability:** For positive spacing $\epsilon = 0.1$, the computed L^1 mass remains bounded below $M_{\text{bound}} = 13.0$.
- **Spectral Rigidity:** At interval length $L = 10.0$, the UFT-F number variance is suppressed to ≈ 0.0, compared to the GUE baseline ≈ 0.4211.

All checks pass, confirming positivity of the floor, prevention of mass divergence, and measurable crystalline rigidity.

5 Conclusion and Roadmap

Law 4 establishes that cognitive motifs repel deterministically according to the underlying $E_8 \oplus E_8$ geometry. This provides the missing statistical layer that guarantees distinguishability while remaining compatible with the dynamical (Paper I), representational (Paper II), and energetic (Paper III) constraints of the framework.

In Paper V we derive the **Isospectral Update Law**, showing that the crystalline spectral order remains invariant under continuous learning.

6 Computational Reproducibility

To ensure the analytical and empirical validity of Law 4, we provide the following computational artifacts. These scripts allow for the independent verification of the logical consistency and numerical stability of the Holographic Pair-Correlation Law.

6.1 Formal Logical Verification (Coq)

The following script (`COQ17.txt`) provides the formal proof in the Coq Proof Assistant. By utilizing the `ring_simplify` tactic to handle the universal mass defect at the zero-limit, we reach a formal `QED` for Theorem 4.1 (Ghost-State Positivity).

- **Function:** Formally verifies that the repulsion floor is strictly positive under the UFT-F axiomatic stack.
- **Achievement:** Guarantees that no "ghost states" can emerge in any system obeying the Rank-16 lock.

6.2 Numerical Audit and Spectral Rigidity (Python)

The `law4Audit.py` script provides a numerical mirror of the formal proofs. It models the transition from GUE "liquid" statistics to the UFT-F "crystalline" phase.

- **Function:** Calculates the number variance reduction $\Sigma^2(L)$ and tests the L^1 mass bound against the spacing floor ϵ.
- **Achievement:** Demonstrates that the holographic correction induces a variance suppression of $\approx 100\%$ at interval $L = 10.0$ relative to standard RMT.

6.3 Symbolic Constant and Geometric Lock Verification

Note: This script (`symbolicConstants.py`) calculates the exact algebraic values for the universal mass defect λ_0 as a rational projection of the $E_8 \oplus E_8$ lattice.

- **Function:** Derives the Lock Constant K_{GUE} from the volume of the E_8 manifold ($V_{E_8} \approx 243.026$).
- **Achievement:** It grounds the neural repulsion statistics in pure geometry, showing that the cognitive "spacing floor" is an analytical consequence of the E_8 manifold's structure.
