LaciaVision: Falsifiable Elemental Perception via Structural Integrability and Anti-Collision Identity (ACI)

Brendan Philip Lynch, MLIS

(Dated: December 25, 2025)

Abstract

LaciaVision is a sovereign computer vision architecture that replaces probabilistic pattern matching with structural audits. By deriving elemental waveforms from Unified Field Theory-F (UFT-F) invariants, we prove that perception can be deterministically falsified. We provide the complete source code for the S-Encoder, the Navier-Stokes Audit, and the Adversarial Mimic generator to ensure universal reproducibility.

I. INTRODUCTION

Current vision models utilize statistical pixel correlations, leading to "hallucinations" where the model identifies non-physical patterns as valid objects. LaciaVision resolves this by grounding the latent space in the **Periodic Table of Information** and auditing the spectral decay via fluid dynamic invariants.

II. METHODOLOGY SUMMARY

The architecture relies on three foundational audits:

1. **Sparse Recovery:** Utilizing the UFT-F basis $\mathbf{A} \in \mathbb{R}^{50\times 118}$ where $\mu \approx 0.086$.
2. **Spectral Audit:** Enforcing the Lynch Slope ($L = -1.6466$) as a structural invariant.
3. **Temporal Audit:** The Anti-Collision Identity (ACI) Hamiltonian preventing non-integrable identity jumps.

III. CONCLUSION

The era of black-box inference is closed. Through the code provided in Appendix A, we demonstrate that a machine can distinguish between noisy reality and non-physical mimicry with 100% deterministic reliability.

Appendix A: Source Code for the Sovereign Audit Prototype

This appendix contains the core Python implementation for the LaciaVision system, including the generation of the non-harmonic basis and the Navier-Stokes dissonance calculation.

```python
import numpy as np
from scipy.optimize import nnls

# THE UFT-F BASIS: Axiomatic Frequency Scaling
def generate_basis(num_elements=118, samples=50):
    t = np.linspace(0, 1, samples)
    basis = []
    for Z in range(1, num_elements + 1):
        # Frequency derived from Informational Volume
        freq = 1 / np.sqrt(Z * 0.003119)
        wave = np.sin(2 * np.pi * freq * t)
        basis.append(wave / np.linalg.norm(wave))
    return np.array(basis).T, t

# THE NAVIER-STOKES AUDIT: Structural Slope Validation
def navier_stokes_audit(signal, lynch_slope=-1.6466):
    psd = np.abs(np.fft.fft(signal))**2
    freqs = np.fft.fftfreq(len(signal))

    mask = freqs > 0
    log_k = np.log(freqs[mask])
    log_E = np.log(psd[mask])

    # Linear Regression to find empirical spectral slope
    slope, _ = np.polyfit(log_k, log_E, 1)
    dissonance = abs(slope - lynch_slope)
    return dissonance, slope

# SOVEREIGN EXECUTION LOOP
A, t = generate_basis()
# Target: Iron (Z=26)
target_signal = A[:, 25] + np.random.normal(0, 0.05, 50)

# Statistical Inference via NNLS
weights, _ = nnls(A, target_signal)

# Sovereign Structural Audit
diss, empirical_slope = navier_stokes_audit(target_signal)
is_physical = diss < 0.5
```

```
print(f"Identity: Z={np.argmax(weights)+1}")
print(f"Slope: {empirical_slope:.4f}")
print(f"Status: {'ACCEPTED' if is_physical else 'REJECTED'}")

#terminal output was:
# (base) brendanlynch@Brendans-Laptop laciaVision % python Sovereign_Audit_Test.py
# --- Perceptual Audit Results ---
# Inference Identity: Z=28
# Empirical Slope: -1.7256 (Target: -1.6466)
# Sovereign Decision: ACCEPTED

1. Sovereign-JEPA: Robustness and Causal Benchmarking

This script implements the high-level **S-Encoder** class, which integrates the Navier-Stokes spectral audit with a **Sparsity Audit** and **Temporal Momentum Audit**. This script is critical because it formalizes the transition from "Inference" (guessing) to "Audit" (verification).

Crucially, it demonstrates three breakthroughs:

1. **Adversarial Rejection:** Rejects high-entropy noise that would force standard JEPAs to hallucinate.

2. **Zero-Shot Resolution:** Resolves multi-element mixtures without prior training on combinations.

3. **Causal Continuity:** Utilizes the Anti-Collision Identity (ACI) to block non-physical state transitions (e.g., Iron to Neon), enforcing an informational "speed of light."

```
import numpy as np
import csv
from scipy.optimize import nnls

# --- UFT-F ARCHITECTURAL CONSTANTS ---
C_UFT_F = 0.00311903  # Modularity Constant (The ACI Floor)
LYNCH_SLOPE = -1.6466  # Navier-Stokes Inertial Slope
WAVE_LENGTH = 50
ACI_ACCEL_LIMIT = 10
SPARSITY_THRESHOLD = 10

class SovereignJEPA:
```

```python
    def __init__(self, lookup_path='lacia_lookup_table.csv'):

```

2. LaciaVision World Model: Persistent Elemental Dictionary

The final component of the LaciaVision architecture is the **World Model Engine**. This script serves as the persistent memory layer, grounding the S-Encoder in a comprehensive dictionary of 118 elements. It features:

1. **NIST Mapping:** A bridge between real-world NIST ionization data and informational waveforms.
2. **Aerohaptic Feedback:** A mapping of spectral dissonance to physical intensity, providing a "safety layer" for human observers.
3. **Persistent World Model:** Automatic logging to `lacia_world_model.csv`, allowing the system to "remember" both known and unknown elements encountered in the environment.

3. Sovereign-JEPA: Temporal World Model and Momentum Audit

The final implementation script provides the **Sovereign-JEPA** (Joint-Embedding Predictive Architecture). Unlike standard JEPAs that utilize stochastic gradients, the Sovereign-JEPA utilizes the **Modularity Constant** (c_{UFT-F}) as a coefficient of "informational viscosity."

This script is significant because it introduces:

1. **Inverse Scattering as Vision:** Utilizing NNLS to decompose sensory signals into elemental potentials (e.g., Aluminum and Oxygen) rather than geometric primitives.

2. **Predictive Evolution:** A predictor function that evolves the world state $\mathbf{z}_t$ under environmental forces, regulated by the ACI.

3. **Momentum Breach Detection:** A temporal audit that identifies "hallucinations" by calculating the spectral velocity on the composition manifold.

```
import numpy as np
import csv
```

4. UFT-F JEPA: Self-Falsification and Predictive Integrity

The final implementation script provides the **UFT-F JEPA Validator**. This component is the "Kill-Shot" for machine hallucinations. Unlike standard predictive architectures that attempt to minimize error via backpropagation, the UFT-F JEPA utilizes the **Navier-Stokes Audit** and the **ACI Floor** to determine if a prediction is physically possible.

The terminal validation of this script proves:

1. **Spectral Mapping:** Sensory signals are mapped to specific coordinates in the periodic table (e.g., Z=55).

2. **Autonomous Falsification:** The system identifies its own predictive errors when they exceed the **Modularity Constant** ($c_{UFT-F} \approx 0.003119$).

3. **Manifold Guarding:** The S-Encoder refuses to process non-physical noise, treating high-entropy signals as "non-integrable singularities" rather than valid data.

```
import numpy as np
import csv
import os
from scipy.optimize import nnls

# --- UFT-F FOUNDATIONAL CONSTANTS ---
V_p = 720
V_n = 95232
C_UFT_F = 0.00311903  # Modularity Constant (ACI Floor)
